이 문서는 정식 R 입문서[?, ?] 매뉴얼이 아닙니다. 이 문서는 R 입문서에 바탕을 둔 예제 Sweave[?, ?] 문서입니다. 이 문서의 목적은 R 입문서를 읽으며 문서에 나와 있는 예제 코드와 그 출력들을 모아 이 문서를 읽는 것으로 실제 R이 어떻게 동작하는 지 (제 스스로 읽고) 이해를 돕는 데 있습니다. 각 단원에 대한 자세한 내용은 해당 R 입문서를 보시고, 이 문서는 보조 이해 수단으로 읽기 바랍니다. Kindle과 같은 작은 디스플레이를 가진 E-book Reader에서 읽기 편하도록 이 문서는 B5 크기로 포맷되었습니다. 이 문서는 소스와 함께 배포될 예정이오니 필요하신 분들은 A4나 letter지 크기로 크기를 조절하셔서 보셔도 좋습니다. 이 문서는 GNU Public License (GPL)/ GNU Free Document License (GFDL) 문서입니다.

1.1 The R environment

R 입문서 참조.¹

¹영어 원본은 [?], 한글 번역본은 [?]를 참조하세요. 일부러 참조하기 편하도록 각 장과 절 번호를 R 입문서 장과 절 번호와 일치시켰습니다. 이미 번역판이 있는데, 굳이 똑 같은 내용을 이 문서에 담아야 할 필요성을 느낄 수 없어 원본 내용은 생략합니다. 또 제가 읽을 것만 추려서 조그맣게 만드려는 애초 목적이 있었습니다. 11장 이후는 아직 R초보자인 저의 이해가 부족해 많이 생략하였습니다. 이 문서는 GPL/GFDL 문서이니 원하시는 대로 수정/배포 가능하니 마음에 안 드시면 편하게 바꾸시든 지 직접 보충해서 사용하시면 되겠습니다. 또 혹시라도 번역 내용을 이 문서에 넣어달라는 요구가 있을까봐 미리 정중히 사양하고 싶습니다.

1.4 R and the window system

1.5 Using R interactively

R 실행 화면에서 프로그램을 끝내고 싶을 때에는 다음과 같이 `q()`를 입력합니다.

```
> q()
```

1.6 An introductory session

R 입문서 참조.

1.7 Getting help with functions and features

R에서 도움말을 얻기 위해서는 다음과 같은 명령들을 입력합니다. 무슨 뜻인 지 전혀 감이 없으시면 `?help`에서 시작하시는 것도 나쁘지 않지요.

```
> help(solve)
> ?solve
> help("[")
> help.start()
> ??solve
> example(topic)
> ?help
```

1.8 R commands, case sensitivity, etc.

1.9 Recall and correction of previous commands

1.10 Executing commands from or diverting output to a file

미리 입력된 명령들을 파일에 담아 통째로 실행시킬 때, `source()` 명령을, 출력 화면을 파일로 리다이렉트할 때에는 `sink` 명령을 씁니다.²

```
> source("commands.R")
> sink("record.lis")
```

1.11 Data permanency and removing objects

오브젝트(변수, 어레이, 문자열, 함수, 따위들)는 R 세션 중 “workspace”에 저장되는 데, 어떻게 있는 지 보고 싶을 때, 지워버리고 싶을 때 다음 명령들을 참조하세요.

```
> rm(list=ls())
> objects()
```

```
character(0)
```

```
> x <- 1+1;x
```

```
[1] 2
```

```
> objects()
```

```
[1] "x"
```

```
> ls()
```

```
[1] "x"
```

R 세션 중에 만들어진 모든 오브젝트는 나중을 위해서 파일에 저장 가능한데요, 보통 세션 종료시에 저장하지 말지 물어보구요, ‘current’ 디렉토리 밑에 ‘.RData’로 저장됩니다. 세션 중에 사용된 명령들은 ‘.Rhistory’란 파일명으로 저장됩니다.

²프로그래밍이 가능해지는 꽤 많은 기능이지요.

2 Simple manipulations; numbers and vectors

2.1 Vectors and assignment

벡터는 갯수(length)와 모드로 나타낼 수 있는 오브젝트이다.

```
> x <- c(10.4, 5.6, 3.1, 6.4, 21.7); x
[1] 10.4  5.6  3.1  6.4 21.7
> assign("x", c(10.4, 5.6, 3.1, 6.4, 21.7)); x
[1] 10.4  5.6  3.1  6.4 21.7
> c(10.4, 5.6, 3.1, 6.4, 21.7) -> x; x
[1] 10.4  5.6  3.1  6.4 21.7
> x = c(10.4, 5.6, 3.1, 6.4, 21.7); x

3 Objects, their modes and attributes

3.1 Intrinsic attributes: mode and length

R 입문서 참조.

함수 `mode(object)`와 `length(object)`는 오브젝트의 모드³와 길이를 파악하는데 사용되지요. 예를 들면,

³모드는 다른 언어의 변수형이나 타입(type)에 해당된다고 이해하면 쉽습니다.

```
> z <- c(1:100); z
```

```
[1] 1 2 3 4 5 6 7 8 9 10 11 12 13

[53] 53 54 55 56 57 58 59 60 61 62 63 64 65
[66] 66 67 68 69 70 71 72 73 74 75 76 77 78
[79] 79 80 81 82 83 84 85 86 87 88 89 90 91
[92] 92 93 94 95 96 97 98 99 100
```

```
> z <- z+1i; z
```

```
[1] 1+1i 2+1i 3+1i 4+1i 5+1i 6+1i 7+1i
[8] 8+1i 9+1i 10+1i 11+1i 12+1i 13+1i 14+1i
[15] 15+1i 16+1i 17+1i 18+1i 19+1i 20+1i 21+1i

[36] 36+1i 37+1i 38+1i 39+1i 40+1i 41+1i 42+1i
[43] 43+1i 44+1i 45+1i 46+1i 47+1i 48+1i 49+1i

[64] 64+1i 65+1i 66+1i 67+1i 68+1i 69+1i 70+1i
[71] 71+1i 72+1i 73+1i 74+1i 75+1i 76+1i 77+1i
[78] 78+1i 79+1i 80+1i 81+1i 82+1i 83+1i 84+1i
[85] 85+1i 86+1i 87+1i 88+1i 89+1i 90+1i 91+1i
[92] 92+1i 93+1i 94+1i 95+1i 96+1i 97+1i 98+1i
[99] 99+1i 100+1i
```

```
> mode(z)
```

```
[1] "complex"
```

```
> length(z)
```

```
[1] 100
```

다른 언어의 형변환(type casting)에 해당하는 모드 변환을 다음과 같이 할 수 있습니다.

```
> z <- 0:9; z
```

```
[1] 0 1 2 3 4 5 6 7 8 9
```

```
> digits <- as.character(z); digits

[1] "0" "1" "2" "3" "4" "5" "6" "7" "8" "9"

> d <- as.integer(digits); d

[1] 0 1 2 3 4 5 6 7 8 9
```

보시는 것처럼 모드 변환을 (integer에서 character로, 그리고 그 역변환인 character에서 integer로) 두 번 거쳐서 d와 z는 같아졌습니다.

3.2 Changing the length of an object

빈(空, empty) 오브젝트도 모드를 가질 수 있지요, 예를 들자면

```
> e <- numeric(); e

numeric(0)
```

위의 e는 numeric 모드의 빈 벡터 구조가 되는 거지요. 비슷하게 character()도 빈 character 벡터 구조를 만듭니다. 어떤 크기든 지 오브젝트가 하나 생기면, 쉽게 새 컴포넌트를 추가할 수 있습니다.

```
> e[3] <- 17; e

[1] NA NA 17
```

위 코드를 실행하면 이제 e는 길이가 3인 벡터가 되는 것이죠. 이런 자동 길이 조정은 아주 자주 쓰입니다. 반대로 벡터를 짝둑 잘라내서 길이를 줄이고 싶을 때는 그렇게 되도록 다시 지정(assignment)해 주면 됩니다.

```
> alpha <- 1:10; alpha

[1] 1 2 3 4 5 6 7 8 9 10

> alpha <- alpha[2*1:5]; alpha

[1] 2 4 6 8 10

> length(alpha) <-3; alpha

[1] 2 4 6
```

위 코드에서 짝수 컴포넌트만 뽑아내는 것이 보이죠.⁴

⁴참 간편하네요. 길이를 강제로 줄여서 벡터를 잘라내는 것도 아주 인상적이네요.

3.3 Getting and setting attributes

함수 `attributes(object)`는 “non-intrinsic” 속성의 전체 리스트를 보여줍니다. 함수 `attr(object, name)`은 *name*으로 선택한 원하는 속성만 보고 싶을 때 쓰지요. `attr(object, name)` 함수가 지정 명령의 왼쪽에 오면 *object*의 속성을 변경하거나 새로운 속성을 추가하는 데 쓰일 수 있습니다. 밑에 예를 보세요.

```
> rm(list=ls())
> z <- 1:100;z

 [1]  1  2  3  4  5  6  7  8  9 10 11 12 13
[14] 14 15 16 17 18 19 20 21 22 23 24 25 26
[27] 27 28 29 30 31 32 33 34 35 36 37 38 39
[40] 40 41 42 43 44 45 46 47 48 49 50 51 52
[53] 53 54 55 56 57 58 59 60 61 62 63 64 65
[66] 66 67 68 69 70 71 72 73 74 75 76 77 78
[79] 79 80 81 82 83 84 85 86 87 88 89 90 91
[92] 92 93 94 95 96 97 98 99 100

> attributes(z)

> attr(z, "dim")

> attr(z, "dim") <- c(10,10);z

  [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10]

3.4 The class of an object

모든 오브젝트는 클래스(class)를 가지고, 함수 `class()`로 확인할 수 있습니다. 단순한 (한 모드로 이루어진) 벡터의 클래스는 바로 모드가 되고요, “matrix”, “array”, “factor”, 그리고 “data.frame”도 가능한 클래스 종류가 됩니다.

이 클래스를 통하여 오브젝트 오리엔티드 프로그래밍을 가능하게 하는 데... 자세한 내용은 R 입문서 참조.

클래스의 효과를 잠시 동안 없애버리려면 함수 `unclass()`를 쓰시면 됩니다.

```
> winter <- as.data.frame(1:10)
> winter

      1:10
1      1
2      2
3      3
4      4
5      5
6      6
7      7
8      8
9      9
10     10

> class(winter)

[1] "data.frame"

> attributes(winter)

$names
[1] "1:10"

$row.names
[1] 1 2 3 4 5 6 7 8 9 10

$class
[1] "data.frame"

> unclass(winter)

$`1:10`
[1] 1 2 3 4 5 6 7 8 9 10
```

```
attr("row.names")
[1] 1 2 3 4 5 6 7 8 9 10

> class(winter)

[1] "data.frame"
```

4 Ordered and unordered factors

R 입문서 참조.

4.1 A specific example

예를 들어 호주⁵ 각 주와 경계에 흠여사는 30명 세무사가 있다고 칩시다. 출신 주를 다음과 같이 표시할 수 있습니다.

```
> state <- c("tas", "sa", "qld", "nsw", "nsw", "nt", "wa", "wa",
+           "qld", "vic", "nsw", "vic", "qld", "qld", "sa", "tas",
+           "sa", "nt", "wa", "vic", "qld", "nsw", "nsw", "wa",
+           "sa", "act", "nsw", "vic", "vic", "act"); state

[1] "tas" "sa"  "qld" "nsw" "nsw" "nt"  "wa"  "wa"  "qld"
[10] "vic" "nsw" "vic" "qld" "qld" "sa"  "tas" "sa"  "nt"
[19] "wa"  "vic" "qld" "nsw" "nsw" "wa"  "sa"  "act" "nsw"
[28] "vic" "vic" "act"

> sort(state)

[1] "act" "act" "nsw" "nsw" "nsw" "nsw" "nsw" "nsw" "nt"
[10] "nt"  "qld" "qld" "qld" "qld" "qld" "sa"  "sa"  "sa"
[19] "sa"  "tas" "tas" "vic" "vic" "vic" "vic" "vic" "wa"
[28] "wa"  "wa"  "wa"
```

`factor()` 함수로 정렬시킬 수 있으며, 정렬됐다는 것은 알파벳 순서대로 줄지었다는 말입니다. `factor()` 함수로 *factor*를 만들 수 있습니다.

```
> statef <- factor(state); statef
```

⁵호주에는 8개 주와 경계가 있다고 합니다. 이름을 들어보면, the Australian Capital Territory, New South Wales, the Northern Territory, Queensland, South Australia, Tasmania, Victoria, 그리고 Western Australia입니다.

```
[1] tas sa qld nsw nsw nt wa wa qld vic nsw vic qld qld
[15] sa tas sa nt wa vic qld nsw nsw wa sa act nsw vic
[29] vic act
Levels: act nsw nt qld sa tas vic wa
```

레벨만 따로 보고 싶으면 `levels()` 함수를 써도 됩니다.

```
> levels(statef)
```

```
[1] "act" "nsw" "nt" "qld" "sa" "tas" "vic" "wa"
```

4.2 The function `tapply()` and ragged array

앞 세무사 예를 이어서, 이제 각 세무사 수입을 다른 벡터로 나타내 봅시다.

```
> incomes <- c(60, 49, 40, 61, 64, 60, 59, 54, 62, 69, 70, 42, 56,
+             61, 61, 61, 58, 51, 48, 65, 49, 49, 41, 48, 52, 46,
+             59, 46, 58, 43); incomes

[1] 60 49 40 61 64 60 59 54 62 69 70 42 56 61 61 61 58 51
[19] 48 65 49 49 41 48 52 46 59 46 58 43
```

각 주별로 수입 표본 평균을 구하기 위해서 `tapply()` 함수를 사용해 봅시다.

```
> incmeans <- tapply(incomes, statef, mean); incmeans

      act      nsw      nt      qld      sa      tas
44.50000 57.33333 55.50000 53.60000 55.00000 60.50000
      vic      wa
56.00000 52.25000
```

각 레벨로 표시된 평균 벡터들이 생겨나지요. `tapply()` 함수는 다른 함수(여기서는 `mean()`)를 첫째 함수 인자(argument)인 `income`에 두번째 인자인 `statef` 레벨에 맞춰 적용하는 것입니다.⁶

```
> incmeans_without_factor <- tapply(incomes, state, mean)
> incmeans_without_factor
```

```
      act      nsw      nt      qld      sa      tas
44.50000 57.33333 55.50000 53.60000 55.00000 60.50000
      vic      wa
56.00000 52.25000
```

⁶음... 참 신기하네요.

이제 주별 수입 평균의 표준 오차(standard error)를 구한다고 칩시다. 표준 오차를 구하는 함수를 우선 만들어 볼까요:

```
> stderr <- function(x) sqrt(var(x)/length(x))
```

자, 이제 `tapply()` 함수를 다시 한 번 새로 정의한 함수로 적용해봅시다.

```
> incster <- tapply(incomes, statef, stderr); incster
```

```
      act      nsw      nt      qld      sa      tas
1.500000 4.310195 4.500000 4.106093 2.738613 0.500000
      vic      wa
5.244044 2.657536
```

```
> lengths <- tapply(incomes, statef, length); lengths
```

```
act nsw  nt qld  sa tas vic  wa
  2   6   2  5   4  2  5   4
```

위 예에서 본 것처럼 (결과) 벡터와 labelling factor를 같이 보여주는 걸 소위 “누더기 어레이”(ragged array)라고 하는데요, 각 subclass의 크기가 제각각이기 (irregular) 때문이지요.

4.3 Ordered factors

5 Arrays and matrices

5.1 Arrays

어레이는 (하나 이상) 차원(Dimension)을 가지는 벡터이다. 150 개 원소로 구성된 벡터 `z`가 있습니다.⁷ *dimension*을 아래처럼 적용해 볼까요?

```
> rm(list=ls())
```

```
> z <- 1:150; z
```

```
[1]  1  2  3  4  5  6  7  8  9 10 11 12 13

⁷원래는 1500 개였는데, 프린트하면 쓸 데 없이 페이지 수가 늘어나기 때문에 제 맘대로 150 개로 줄였습니다.

`matrix()` 나 `array()` 같은 함수로 간단히 자연스럽게 어레이를 만들 수 있습니다. 일차원 어레이도 있지만, 그런 어레이는 대개 벡터와 마찬가지로 취급받습니다. 벡터가 있는 데, 일부러 일차원 어레이를 만들 필요는 없겠지요.

5.2 Array indexing. Subsections of an array

R 입문서 참조.

```
> a <- 1:(2*4*2); dim(a) <- c(2,4,2); a[, , ]  
  
      [,1] [,2] [,3] [,4]  
[1,]     1     3     5     7

> dim(a); dim(a[2, , ])  
[1] 2 4 2

```

5.3 Index matrices

예를 먼저 보고, 인덱스 행렬(index matrix)이 뭔 지 감을 잡아볼까요? 예를 들어, 4x5 크기 어레이 X가 있고, 다음을 해보려 합니다.

- $X[1,3]$, $X[2,2]$, 그리고 $X[3,1]$ 의 원소를 추출
- 추출된 항목 자리를 0으로 바꾸기

```
> x <- array(1:20, dim=c(4,5)); x

      [,1] [,2] [,3] [,4] [,5]
[1,]    1    5    9   13   17
[2,]    2    6   10   14   18
[3,]    3    7   11   15   19
[4,]    4    8   12   16   20

> i <- array(c(1:3,3:1), dim=c(3,2)); i

      [,1] [,2]
[1,]    1    3
[2,]    2    2
[3,]    3    1

> x[i] <-0
> x
```

```
      [,1] [,2] [,3] [,4] [,5]
[1,]    1    5    0   13   17
[2,]    2    0   10   14   18
[3,]    0    7   11   15   19
[4,]    4    8   12   16   20
```

위 예에서 어레이 *i*는 인덱스 행렬입니다.

부정(negative) 인덱스는 인덱스 행렬에 사용할 수 없습니다. NA나 0은 사용 가능합니다. 예를 더 들어 보겠습니다.

```
> blocks <- 1:4; blocks

[1] 1 2 3 4

> b <- length(levels(factor(blocks))); b

[1] 4
